

# Pandas

import numpy as np

import pandas as pd

In: dict 1 = { "name": ['harry', 'rohan', 'skill f', 'shubh'],  
"marks": [90, 87, 63, 74],  
"city": ['rampur', 'delhi', 'kolkata', 'Mumbai'] }

In: df = pd.DataFrame(dict 1)

In: df

both DF are Capital

Out: forms a table to analyse the data in a better way  
↓  
also gives index to each row

In: df.to\_csv('file.csv') → to import df to spreadsheet

In: df.to\_csv('file.csv', index=False)  
→ to make a spread sheet which does not contain the index

In: df.head(2)

In: df.tail(2)

} no. of rows to be seen

In: df.describe()

Output: find mean,  $\sigma$ ,  $\sigma^2$ , count etc of all the columns containing numerical value.

In: `harry = pd.read_csv('name.csv')`

↳ to read a spread sheet

In: `harry['column name']`

↳ prints the particular column

In: `harry['column name'][0] = 50`

↳ change the value

In: `harry.index = ['a', 'b', 'c', 'd']`

↳ to change the indexing

In: 

|  |                |                |                |                |                |
|--|----------------|----------------|----------------|----------------|----------------|
|  | C <sub>1</sub> | C <sub>2</sub> | C <sub>3</sub> | C <sub>4</sub> | C <sub>5</sub> |
|  |                |                |                |                |                |
|  |                |                |                |                |                |
|  |                |                |                |                |                |
|  |                |                |                |                |                |

one series

a series consist of row (column containing same element)

↳ Data Frame

In: `ser = pd.Series(np.random.rand(3))`

In: `ser` ↳ outputs a series from (0,1,2)

In: `type(ser)` ↳ `Series`

In: `newdf = pd.DataFrame(np.random.rand(334, 5))`

↳ 2D array (row x column) creates a new data frame.

334 rows  
5 col  
(334, 5)  
index = np.arange(334)

In: new df . index → prints index (0-333)

In: new df . column → prints column (0-4)

In: newdf . to\_numpy()

↳ converts the table  
to a numpy array

In: newdf . T

↳ transpose of the table  
(index  $\Rightarrow$  column)

In: newdf . sort\_index (axis=0, ascending=False)

(ascending=True, by default) ↳ upside-down of the table

In: newdf . sort\_index (axis=1, ascending=False)

↳ lateral inversion of the table

In: newdf [0]

↓  
series

prints the column 0

In: newdf2 = newdf

( newdf2 is basically  
a view of newdf

In: newdf2 [0] [0] = 9783

In: new df → changes

↓  
newdf2 is pointing  
towards newdf

so when we change  
newdf2, newdf  
also changes

In: `newdf2 = newdf[1:]` or `newdf.copy()`

→ now on changing `newdf2`, `newdf` will not change

In: `newdf.loc[0,0] = 654`

correct way to change any element

In: `newdf.column = list("ABCDE")`

|   | A | B | C | D | E |
|---|---|---|---|---|---|
| 0 |   |   |   |   |   |
| 1 |   |   |   |   |   |
| 2 |   |   |   |   |   |
| 3 |   |   |   |   |   |

In: `newdf.drop(0, axis=1)`

remove from column=0

In: `newdf.loc[[1,2], ['c', 'd']]`

will give only a part of the table

(if `newdf = newdf.loc[[1,2], ['c', 'd']]`  
or then `newdf` would have changed to  
(if we write `inplace=True`) this shorter table)

In: `newdf.loc[:, ['c', 'd']]`

prints entire 'c' & 'd' column

In: `newdf.loc[[1,2], :]`

prints entire row 1 & 2

In: newdf.loc [(newdf['A'] < 0.3)] <sub>condition</sub> <sub>==</sub>

In: newdf.iloc [0,4] <sub>only indexing</sub>

In: newdf['B'].isnull() <sub>bool</sub> <sub>== newdf['B'].nonnull()</sub>

In: newdf.loc['B'] = None <sub>changes to None</sub>

In: newdf.info()

In: newdf.describe()

In: newdf['A'].value\_counts()

---
